Abstract

We examine the asymptotics of a sequence of lacunary binomial-type polynomials $\wp_n(z)$ as $n \rightarrow \infty$ that have arisen in the problem of the expected number of independent sets of vertices of finite simple graphs. We extend the recent analysis of Gawronski and Neuschel by employing the method of steepest descents applied to an integral representation. The case of complex z with $|z| < 1$ is also considered. Numerical results are presented to illustrate the accuracy of the resulting expansions.

Mathematics Subject Classification: 30E15, 41A60

Keywords: Asymptotics, lacunary polynomials, saddle points

1. Introduction

The sequence of lacunary binomial-type polynomials defined by

$$\wp_n(z) = \sum_{k=0}^n \binom{n}{k} z^{k(k-1)/2} \quad (1.1)$$

has been encountered by Brown *et al.* [1] in connection with the problem of the expected number of independent sets of vertices of finite simple graphs. These authors obtained upper and lower bounds for the values of $\wp_n(z)$ for $0 < z < 1$ and, based on analytic results and numerical computations, made the following conjecture on its asymptotic behaviour as $n \rightarrow \infty$

$$\wp_n(1/y) \sim \frac{1}{\sqrt{w(n)}} \exp\left(\frac{w(n)^2 + 2w(n)}{2 \log y}\right) \quad (1.2)$$

when $y > 1$. Here, $w(n) = W(n\sqrt{y} \log y)$, where $W(a)$ denotes the Lambert W -function which, for $a > 0$, is defined as the positive solution of the equation $te^t = a$ [4, p. 111].

Recently, Gawronski and Neuschel [3] considered an integral representation for $\wp_n(z)$ and employed a path displacement argument in the complex plane combined with a non-standard version of the saddle-point method to obtain the asymptotic formula when $y > 1$

$$\wp_n(1/y) = \frac{1}{\sqrt{r(n)}} \exp\left(\frac{r(n)^2 + 2r(n)}{2 \log y}\right) \{\Theta(y) + o(1)\} \quad (1.3)$$

as $n \rightarrow \infty$, where

$$\Theta(y) = 1 + 2 \sum_{k=1}^{\infty} e^{-2\pi^2 k^2 / \log y} \cos \left(\frac{2\pi k r(n)}{\log y} \right) \quad (1.4)$$

and the quantity $r(n)$ is defined as the positive solution of the equation

$$t(e^t + \sqrt{y}) = n\sqrt{y} \log y.$$

It was established in [3] that the expression in front of the curly braces in (1.3) is asymptotically equivalent to the conjectured approximation in (1.2) in the limit $n \rightarrow \infty$.

In this paper, we consider the same integral representation for $\wp_n(z)$ as derived in [3] and employ the method of steepest descents to determine a more accurate expansion for moderately large values of n . We also discuss the case of complex z satisfying $|z| < 1$. We present numerical computations to demonstrate the accuracy of our expansion and the approximation in (1.3).

2. An integral representation and saddle-point structure when $z < 1$

For convenience in presentation we set throughout $z = 1/x^2$, where $|x| > 1$ with $|\arg x| \leq \frac{1}{2}\pi$. Substituting the standard result (cf. [4, Eq. (7.7.3)])

$$x^{-k^2} = \frac{1}{2\sqrt{\pi \log x}} \int_{-\infty}^{\infty} \exp \left(-\frac{s^2}{4 \log x} + iks \right) ds \quad (|x| > 1)$$

into (1.1), followed by an interchange in the order of summation and integration and use of the binomial theorem, we obtain the integral representation derived in [3]

$$\begin{aligned} \wp_n(x^{-2}) &= \frac{1}{2\sqrt{\pi \log x}} \int_{-\infty}^{\infty} \exp \left(\frac{-s^2}{4 \log x} \right) (1 + xe^{is})^n ds \\ &= \frac{1}{2\sqrt{\pi \log x}} \int_{-\infty}^{\infty} e^{-n\psi(s)} ds, \end{aligned} \quad (2.1)$$

where

$$\psi(s) = \frac{s^2}{4n \log x} - \log(1 + xe^{is}). \quad (2.2)$$

We proceed in Section 3 with the determination of the asymptotics of the integral in (2.1) for $n \rightarrow \infty$ and finite real x by application of the method of steepest descents. In Section 4 we extend these considerations to complex x . Before doing this we first examine the saddle-point structure of the phase function $\psi(s)$ when x is real and $x > 1$.

The saddle points s_k of $\psi(s)$ are given by $\psi'(s) = 0$, or

$$s_k e^{-is_k} (1 + xe^{is_k}) = 2inx \log x. \quad (2.3)$$

There is a single saddle situated on the imaginary axis together with two infinite strings of saddles symmetrically positioned about $\text{Re}(s) = 0$ resulting from the periodicity of the function e^{is} . If we write

$$s_k = \sigma_k + 2\pi k \quad (2.4)$$

for integer k we have from (2.3), with $\alpha := 2x \log x$,

$$\log(\sigma_k + 2\pi k) - i\sigma_k + \log(1 + xe^{i\sigma_k}) = \log(in\alpha).$$

A straightforward perturbative solution of this equation for large n can be obtained by putting $\sigma_k = i \log n - \epsilon$, where $|\epsilon| \ll \log n$, to find

$$\epsilon \simeq i(\log \log n - \log \alpha) + i \log \left(1 - \frac{i(2\pi k - \log \log n)}{\log n} \right).$$

This yields the approximation valid for large n and bounded k given by

$$\sigma_k \simeq i \log \left(\frac{n\alpha}{\log n} \right) - i \log \left(1 - \frac{i(2\pi k - \log \log n)}{\log n} \right). \quad (2.5)$$

The saddle on the imaginary axis corresponding to $k = 0$ is

$$s_0 = \sigma_0 = ir(n), \quad r(n) \simeq \log \left(\frac{n\alpha}{\log n} \right) + \frac{\log \log n}{\log n}. \quad (2.6)$$

Provided $2\pi|k| \ll \log n$, the saddles with $|k| \geq 1$ have from (2.5) the approximate location

$$\sigma_k \simeq -\frac{2\pi k}{\log n} + i \left\{ r(n) - \frac{1}{2} \left(\frac{2\pi k - \log \log n}{\log n} \right)^2 \right\}. \quad (2.7)$$

This last result indicates that the first few saddles situated in the right and left half-planes have $\text{Im}(s_k) \simeq r(n)$ for $n \rightarrow \infty$. However, the value of n required for the validity of this approximation is extremely large. When $k = \pm 1$, the requirement $2\pi|k|/\log n = 10^{-1}$, for example, yields $n = e^{20\pi} \simeq 2 \times 10^{27}$. For moderately large n the values of $\text{Im}(s_k)$ for $|k| \geq 1$ are found to be significantly less than $r(n)$; see Table 1.

Table 1: The location of the saddles s_k for $0 \leq k \leq 5$ and their approximate values from (2.5) when $n = 1000$, $x = 2$. The saddles $s_{-k} = -\bar{s}_k$, where the bar denotes the complex conjugate.

k	s_k	Approximate s_k
0	6.112742i	6.323089i
1	5.521734 + 5.839316i	5.382118 + 5.846300i
2	11.427821 + 5.387286i	11.372547 + 5.323709i
3	17.544733 + 5.019893i	17.536813 + 4.957375i
4	23.741718 + 4.737505i	23.757372 + 4.684147i
5	29.972889 + 4.513009i	30.002189 + 4.467837i

The paths of steepest descent, which we denote by \mathcal{C}_k , and ascent are given by the paths on which

$$\text{Im}(\psi(s) - \psi(s_k)) = 0.$$

The steepest descent paths can terminate either at infinity in the sectors $|\arg s| < \frac{1}{4}\pi$ or at the points where $(1 + xe^{is}) = 0$; that is, at the logarithmic singularities of $\psi(s)$ given by

$$T_k = i \log x + (2k + 1)\pi \quad (k \in \mathbb{Z}). \quad (2.8)$$

It is found (we omit these details) that as $k \rightarrow \pm\infty$ the saddles s_k approach the points T_k in (2.8). Paths of steepest ascent terminate at infinity in the sectors $|\arg(\pm is)| < \frac{1}{4}\pi$. An example of the distribution of the saddles and the paths of steepest descent and ascent is shown in Fig. 1. The case of complex x is deferred to Section 4.

Figure 1: The steepest descent paths \mathcal{C}_k through the saddles s_k (heavy dots) with $|k| \leq 2$ and the associated logarithmic singularities T_k given by (2.8) when $n = 200$, $x = 2$. The steepest ascent paths pass to infinity parallel to the imaginary s -axis.

3. Derivation of the expansion for $x > 1$

By a standard application of Cauchy's theorem we can shift the integration path in (2.1) from the real s -axis to a parallel line through the points T_k (where the integrand vanishes), and thence to coincide with the steepest descent paths \mathcal{C}_k through the saddles s_k . Our final integration path then takes on a “serpentine” form as it passes over each saddle in turn. Hence we can write (when x is real)

$$\wp_n(x^{-2}) = J_0 + 2\operatorname{Re} \sum_{k=1}^{\infty} J_k, \quad (3.1)$$

where

$$J_k = \frac{1}{2\sqrt{\pi \log x}} \int_{\mathcal{C}_k} e^{-n\psi(s)} ds. \quad (3.2)$$

We present only the calculation of the expansion of J_0 , since the details for J_k ($k \geq 1$) are similar. We define the quantities

$$\lambda_k := x e^{is_k}, \quad a_k := \frac{(1 + \lambda_k)^2}{4n\lambda_k \log x}, \quad \omega_k := \frac{2n\lambda_k \log x}{(1 + \lambda_k)^2} \quad (k \geq 0), \quad (3.3)$$

so that

$$\psi''(s_0) = \frac{1}{2n \log x} + \frac{\lambda_0}{(1 + \lambda_0)^2} = \frac{1 + \omega_0}{2n \log x}.$$

Then application of the method of steepest descents [4, p. 48] produces

$$J_0 \sim \frac{e^{-n\psi(s_0)}}{\sqrt{2\pi\psi''(s_0)\log x}} \sum_{j=0}^{\infty} \frac{\Gamma(j + \frac{1}{2}) d_{j0}}{n^{j+\frac{1}{2}}}$$

as $n \rightarrow \infty$. The coefficients d_{j0} ($0 \leq j \leq 3$) are given by [2, p. 119], [5, p. 13]

$$d_{00} = 1, \quad d_{10} = \frac{1}{12\psi''(s_0)}(5p_3^2 - 3p_4),$$

$$d_{20} = \frac{1}{864(\psi''(s_0))^2}(385p_3^4 - 630p_3^2p_4 + 168p_3p_5 + 105p_4^2 - 24p_6),$$

$$d_{30} = \frac{1}{777600(\psi''(s_0))^3}(425425p_3^6 - 1126125p_3^4p_4 + 675675p_3^2p_4^2 - 51975p_4^3 + 360360p_3^3p_5 - \\ - 249480p_3p_4p_5 + 13608p_5^2 - 83160p_3^2p_6 + 22680p_4p_6 + 12960p_3p_7 - 1080p_8),$$

where, for convenience in presentation, we have defined

$$p_r := \frac{\psi^{(r)}(s_0)}{\psi''(s_0)} \quad (r \geq 3).$$

Insertion of the values of the derivatives of $\psi(s)$ evaluated at s_0 then yields after some algebra with the help of *Mathematica* the coefficients in the form

$$d_{00} = 1, \quad d_{10} = \frac{-Q_1(a_0, \lambda_0)}{6(1 + 2a_0)^3\lambda_0},$$

$$d_{20} = \frac{Q_2(a_0, \lambda_0)}{216(1 + 2a_0)^6\lambda_0^2}, \quad d_{30} = \frac{Q_3(a_0, \lambda_0)}{97200(1 + 2a_0)^9\lambda_0^3}.$$

The quantities $Q_j(a_0, \lambda_0)$ are defined in the Appendix in terms of polynomials in λ_0 .

From (2.3), (2.6) and (3.3) it is easy to see that

$$\sigma_0 \sim \log n, \quad e^{\sigma_0} \sim \frac{2nx \log x}{\log n}, \quad \lambda_0 \sim \frac{\log n}{2n \log x} \quad a_0 \sim \frac{1}{2 \log n} \quad (n \rightarrow \infty).$$

If we define the coefficients c_{j0} by

$$c_{00} = 1, \quad c_{10} = \frac{-Q_1(a_0, \lambda_0)\chi}{6(1 + 2a_0)^3}, \\ c_{20} = \frac{Q_2(a_0, \lambda_0)\chi^2}{216(1 + 2a_0)^6}, \quad c_{30} = \frac{Q_3(a_0, \lambda_0)\chi^3}{97200(1 + 2a_0)^9}, \quad (3.4)$$

where we have put $\chi \equiv \log n/(n\lambda_0)$, it follows from (A.1) that

$$c_{10} \sim -\frac{1}{3} \log x, \quad c_{20} \sim \frac{1}{54}(\log x)^2, \quad c_{30} \sim \frac{139}{12150}(\log x)^3$$

as $n \rightarrow \infty$, and therefore that $c_{j0} = O(1)$ ($1 \leq j \leq 3$) in this limit. Then we obtain finally

$$J_0 \sim \frac{e^{-n\psi(s_0)}}{\sqrt{1 + \omega_0}} \sum_{j=0}^{\infty} \frac{(\frac{1}{2})_j c_{j0}}{(\log n)^j} \quad (n \rightarrow \infty), \quad (3.5)$$

where $(\frac{1}{2})_j = \Gamma(j + \frac{1}{2})/\Gamma(\frac{1}{2})$ is Pochhammer's symbol and $\sum_{j=0}$ means that the sum is restricted to the first few terms of the series. The quantity $\omega_0 \sim \log n$ as $n \rightarrow \infty$. We remark that a full treatment would require a knowledge of the behaviour of the coefficients in general as $n \rightarrow \infty$ to establish the asymptotic nature of (3.5); we do not carry this out here.

The calculation of the integrals J_k ($k \geq 1$) follows the same procedure and we find

$$J_k \sim \frac{e^{-n\psi(s_k)}}{\sqrt{1+\omega_k}} \sum_{j=0} \frac{(\frac{1}{2})_j c_{jk}}{(\log n)^j} \quad (n \rightarrow \infty), \quad (3.6)$$

where the first few coefficients c_{jk} are defined in (3.4) with a_0 and λ_0 replaced by a_k and λ_k . In terms of the quantities σ_k defined in (2.4), we have

$$\psi(s_k) = \psi(\sigma_k) + \frac{\pi^2 k^2 + \pi k \sigma_k}{n \log x}.$$

Then the expansion of $\wp_n(x^{-2})$ when $x > 1$ is given by the following theorem.

Theorem 1 *For real x satisfying $x > 1$ we have from (3.1) the expansion*

$$\begin{aligned} \wp_n(x^{-2}) \sim & \frac{e^{-n\psi(\sigma_0)}}{\sqrt{1+\omega_0}} \sum_{j=0} \frac{(\frac{1}{2})_j c_{j0}}{(\log n)^j} \\ & + 2Re \sum_{k=1}^{\infty} \exp\left(-\frac{\pi^2 k^2 + \pi k \sigma_k}{\log x}\right) \frac{e^{-n\psi(\sigma_k)}}{\sqrt{1+\omega_k}} \sum_{j=0} \frac{(\frac{1}{2})_j c_{jk}}{(\log n)^j} \end{aligned} \quad (3.7)$$

as $n \rightarrow \infty$. The coefficients c_{jk} and the quantities σ_k and ω_k are defined in (3.4), (2.4) and (3.3), respectively.

From (2.7), the saddles with finite k approximately satisfy $\sigma_k \simeq ir(n) \simeq i \log n$ and $\omega_k \simeq \log n \simeq r(n)$ as $n \rightarrow \infty$. Since, with this approximation,

$$-\psi(\sigma_k) \simeq \frac{r(n)^2}{4n \log x} + \log\left(1 + \frac{r(n)}{2n \log x}\right) \simeq \frac{r(n)^2 + 2r(n)}{4n \log x} \quad (n \rightarrow \infty),$$

it is seen that the leading terms of (3.7) agree with the result (1.3) (with $y = x^2$) obtained by Gawronski and Neuschel [3].

In Table 2 we show the absolute relative error in the computation of $\wp_n(x^{-2})$ for different n and x using the asymptotic expansion (3.7) as a function of the truncation index j in the dominant sum (corresponding to $k = 0$). Table 3 compares the value of $\wp_n(x^{-2})$ with that obtained from (3.7) (with truncation index $j = 3$ in the dominant sum) and the approximation (1.3). In each table two terms have been employed in the sum with $k = 1$, with the contributions from the sums with $k \geq 2$ being negligible on account of the $\exp(-\pi^2 k^2 / \log x)$ dependence. It is seen that for the values of n chosen ($n \leq 1000$) the formula (1.3) gives only a gross approximation, whereas (3.7) yields very good agreement.

4. The case of complex x

We now consider x to be a complex variable and write $x = |x|e^{i\theta}$, where it will be sufficient to restrict our attention to values of the phase θ satisfying $0 \leq \theta \leq \frac{1}{2}\pi$. In terms of the

original variable z this corresponds to $0 \leq \arg z \leq \pi$. When $\theta > 0$, it can be seen from (2.5) and (2.8) that both the saddles s_k and the logarithmic singularities T_k are displaced to the left¹; see Fig. 2. A more significant difference between the $\theta = 0$ and $\theta > 0$ cases, however, is the connectivity of the saddles.

When $\theta = 0$, it is found that $\text{Im}(\psi(s_k))$ increases monotonically with k and all the paths of steepest descent through the saddles s_k have their endpoints at their associated logarithmic singularities T_{k-1} and T_k ; see Fig. 1. When $\theta > 0$, the quantities $\text{Im}(\psi(s_k))$ attain a maximum for a certain $k \geq 1$ and thereafter decrease monotonically with k . This results in a Stokes phenomenon occurring at an infinite sequence of θ -values when a pair of adjacent saddles connects; see Table 4.

We illustrate this situation in Fig. 2 for the particular case $n = 100$, $|x| = 3$. Fig. 2(a) shows the topology of the steepest descent paths C_k through the saddles for $0.22172\pi < \theta \leq \frac{1}{2}\pi$. These paths with $k \leq 0$ are similar to those in Fig. 1, but the paths C_k with $k \geq 1$ emanate from the logarithmic singularities T_k and pass to infinity in the direction $\arg s \simeq \theta/(2 \log |x|)$. The contribution to $\wp_n(x^{-2})$ in this case results only from the saddles with $k \leq 1$. Fig. 2(b) shows the critical value $\theta = 0.22172\pi$ where the saddles s_1 and s_2 connect to produce a Stokes phenomenon. Fig. 2(c) illustrates the topology of the steepest descent paths for θ in the range $0.09844\pi < \theta < 0.22172\pi$, where $\wp_n(x^{-2})$ picks up an additional contribution from the saddle s_2 . Finally, Fig. 2(d) shows the next critical value $\theta = 0.09844\pi$ where the saddles s_2 and s_3 connect to produce another Stokes phenomenon. If we denote by $K(\theta)$ the number of contributing saddles situated in $\text{Re}(s) > 0$, then $K(\theta) = 1$ for $0.22172\pi < \theta \leq \frac{1}{2}\pi$ and $K(\theta) = 2$ for $0.09844\pi < \theta < 0.22172\pi$. This process of

¹When $\theta < 0$ the situation is reversed: the saddles and the points T_k are displaced to the right.

Table 4: Values of the phase θ when the saddles s_k, s_{k+1} (with $1 \leq k \leq 5$) connect to produce a Stokes phenomenon.

Saddles	$n = 200, x = 2$ θ/π	$n = 100, x = 3$ θ/π
s_1, s_2	0.12796	0.22172
s_2, s_3	0.05859	0.09844
s_3, s_4	0.03617	0.06070
s_4, s_5	0.02534	0.04264
s_5, s_6	0.01907	0.03220

connecting pairs of saddles continues as θ approaches zero with the result that progressively more saddles contribute to the sum $\wp_n(x^{-2})$. When $\theta = 0$, there are no such connections ($K(0) = \infty$) and all the saddles contribute to yield the result in (3.7).

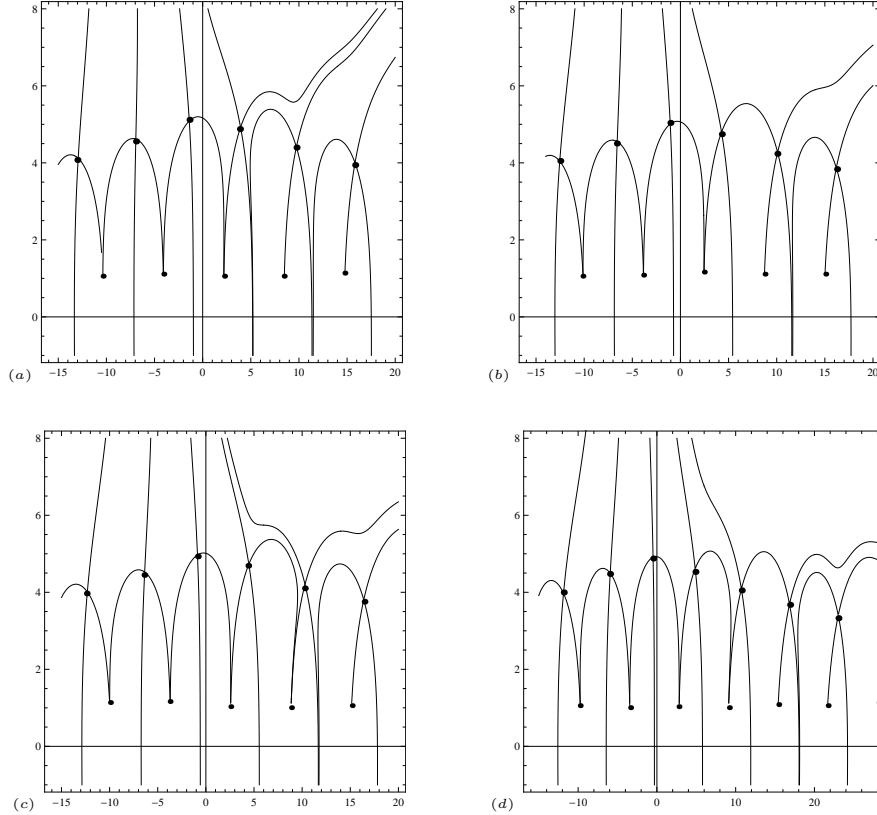

Figure 2: The steepest descent paths C_k through the saddles s_k (heavy dots) with $-2 \leq k \leq 3$ (including s_4 in (d)) when $n = 100$, $x = 3e^{i\theta}$: (a) $\theta = 0.30\pi$, (b) $\theta = 0.22172\pi$, (c) $\theta = 0.18\pi$, (d) $\theta = 0.09844\pi$. A Stokes phenomenon occurs in (b) and (d) where the two adjacent saddles s_1, s_2 and s_2, s_3 become connected.

In view of the above discussion, the expansion of $\wp_n(x^{-2})$ for complex x when $|x| > 1$

Figure 3: Values of $\log_{10} |J_k|$ for $k \leq 1$ when $n = 200$ and $\theta = 0.40\pi$: (a) $|x| = 1.50$ and (b) $|x| = 1.10$.

and $0 \leq \theta \leq \frac{1}{2}\pi$ is given by

$$\wp_n(x^{-2}) \sim \sum_{k=-\infty}^{K(\theta)} J_k, \quad (4.1)$$

where the contributions J_k have the expansions given in (3.5) and (3.6). The upper limit $K(\theta)$ varies with θ : the precise transitions in $K(\theta)$ as θ decreases from $\frac{1}{2}\pi$ will depend on the values of n and $|x|$.

Table 5: The absolute relative error in the computation of $\wp_n(x^{-2})$ for different n and complex x using (4.1).

θ/π	$n = 200, x = 1.20$	$n = 200, x = 1.50$	$n = 1000, x = 2.00$
0	5.919×10^{-9}	5.329×10^{-7}	2.206×10^{-6}
0.10	3.391×10^{-7}	1.303×10^{-6}	3.564×10^{-6}
0.20	4.315×10^{-7}	3.413×10^{-6}	3.216×10^{-6}
0.30	3.856×10^{-7}	1.077×10^{-5}	6.450×10^{-6}
0.40	2.808×10^{-7}	7.425×10^{-6}	1.029×10^{-5}
0.50	5.379×10^{-8}	4.089×10^{-6}	2.245×10^{-6}

In Table 5 we present the absolute relative error in the computation of $\wp_n(x^{-2})$ for complex x for different n and $|x|$ using (4.1). In each case we have employed the truncation index $j = 3$ in the expansions of J_k . A feature of these calculations that is worthy of note is the location of the dominant saddles. When $\theta = 0$, the dominant saddle corresponds to $k = 0$ and the saddles with $k = \pm 1$ yield a very small contribution. As $|x| \rightarrow 1$ and $\theta \rightarrow \frac{1}{2}\pi$ (that is, $|z| \rightarrow 1$ and $\arg z \rightarrow \pi$), the dominant saddles progressively shift to more negative k -values and, moreover, more saddles are found to make a significant contribution to $\wp_n(x^{-2})$. This last fact makes the calculation of $\wp_n(x^{-2})$ more difficult to determine in this limit. We illustrate this feature in Fig. 3 where we display examples of the values of $\log_{10} |J_k|$ against the index k .

Appendix: The quantities $Q_j(a_0, \lambda_0)$

In this appendix we display the quantities $Q_j(a_0, \lambda_0)$ appearing in the coefficients c_{j0} in

(3.4) for $1 \leq j \leq 3$. These have the form

$$\begin{aligned} Q_1(a_0, \lambda_0) &= P_{11}(\lambda_0) - 3a_0P_{12}(\lambda_0), \\ Q_2(a_0, \lambda_0) &= P_{21}(\lambda_0) - 6a_0P_{22}(\lambda_0) + 3a_0^2P_{23}(\lambda_0) - 48a_0^3P_{24}(\lambda_0), \\ Q_3(a_0, \lambda_0) &= P_{31}(\lambda_0) + 27a_0P_{32}(\lambda_0) - 9a_0^2P_{33}(\lambda_0) + 27a_0^3P_{34}(\lambda_0) \\ &\quad - 432a_0^4P_{35}(\lambda_0) + 4320a_0^5P_{36}(\lambda_0), \end{aligned} \quad (\text{A.1})$$

where the $P_{jk}(\xi)$ ($1 \leq k \leq 2j$) are polynomials in ξ of degree $2j$ given by

$$\begin{aligned} P_{11}(\xi) &= 1 + \xi + \xi^2, & P_{12}(\xi) &= 1 - 4\xi + \xi^2, \\ P_{21}(\xi) &= (1 + \xi + \xi^2)^2, & P_{22}(\xi) &= 13 + 5\xi - 10\xi^2 + 5\xi^3 + 13\xi^4, \\ P_{23}(\xi) &= 67 - 328\xi + 278\xi^2 - 328\xi^3 + 67\xi^4, & P_{24}(\xi) &= 1 - 26\xi + 66\xi^2 - 26\xi^3 + \xi^4, \\ P_{31}(\xi) &= 139 + 417\xi + 402\xi^2 + 109\xi^3 + 402\xi^4 + 417\xi^5 + 139\xi^6, \\ P_{32}(\xi) &= 151 + 378\xi + 308\xi^2 + 56\xi^3 + 308\xi^4 + 378\xi^5 + 151\xi^6, \\ P_{33}(\xi) &= 9271 - 3497\xi - 10867\xi^2 + 766\xi^3 - 10867\xi^4 - 3497\xi^5 + 9271\xi^6, \\ P_{34}(\xi) &= 7349 - 48668\xi + 45007\xi^2 - 24056\xi^3 + 45007\xi^4 - 48668\xi^5 + 7349\xi^6, \\ P_{35}(\xi) &= 203 - 5016\xi + 18729\xi^2 - 24392\xi^3 + 18729\xi^4 - 5016\xi^5 + 203\xi^6, \\ P_{36}(\xi) &= 1 - 120\xi + 1191\xi^2 - 2416\xi^3 + 1191\xi^4 - 120\xi^5 + \xi^6. \end{aligned}$$

The coefficients c_{jk} associated with the k th saddle follow from the expressions above and (3.4) with a_0 and λ_0 replaced by a_k and λ_k defined in (3.3).
